PEAT AND PEAT DEPOSITS IN IOWA

Introduction. During the summer of 1905 the Iowa Geological Survey detailed Mr. L. H. Wood to locate and determine the area and thickness of the leading peat swamps in Iowa. On the basis of Mr. Wood's notes, Mr. T. E. Savage, then Assistant State Geologist, prepared "A Preliminary Report on the Peat Resources of Iowa" which appeared early in 1906 as Bulletin 2 of the Survey. Several of the county reports published before the appearance of the bulletin casually mentioned the peat deposits within their borders, and all of those published since having to do with counties within the peat area mention and some describe their peat resources.

Several attempts have been made to utilize Iowa peat, notably near Dows in Franklin county and at Goose Lake near Fertile in Worth county. Both plants have not yet passed the experimental stage. Interest in the possibilities of the state's resources in peat has been stimulated greatly by the preliminary work of the Survey, and hence the reason for the present more extended inquiry.

During portions of the summers of 1907 and 1908 Mr. W. F. Coover, assisted by Mr. F. A. Knowles during 1908, mapped and sampled the more important bogs in the state. The work of sampling was made difficult because of the protracted wet weather during the field seasons. Bogs containing less than forty acres were not sampled, as a rule, and no samples were saved in those where the vegetable debris averaged less than three feet in thickness. A two-inch common auger was used both for testing depth and securing samples. In general, all of the borings of a hole were mixed and constituted but a single sample. Where considerable changes in character and quality of material were noted an additional sample was sometimes taken. The samples were numbered and shipped to headquarters for further study and analysis.

Peat Defined. Ordinary vegetable matter according to standard authorities is composed of two compounds, cellulose (C_6H_{10} O_5) or vegetable fiber, and lignin ($C_{35}H_{24}O_{20}$) or ordinary wood fiber. Nitrogen in small quantities is generally associated with the two preceding.

Both cellulose and lignin are unstable under atmospheric conditions and tend to break down to much more simple compounds, chief of which are members of the marsh gas series, carbonic acid gas and water. In air the destruction of vegetable matter is almost complete, leaving behind only the inorganic residue. similar in character to the ash residue which remains after burning wood. In fact, slow exidation in air under natural conditions produces results practically parallel to those produced by rapid oxidation through burning. In the case of plant remains which accumulate under water, the process of simplification is interfered with and only a partial chemical breaking down is the result. The principal changes which take place are a relative loss in oxygen and hydrogen and an increase in carbon. The resultant partially decayed plant debris is known as peat. From the above it is evident that the physical constitution and chemical composition must be highly variable. Physically peat varies from a highly fibrous, heterogeneous lace work of almost unchanged plant remains to a fiberless, homogeneous, structureless muck or mud. In the first the original plants are easily identified, while in the latter the organic origin can be determined only through the assistance of the compound microscope.

In composition the variation is important but less easily marked. The carbon percentage ranges from about forty to over sixty. In color Iowa peat ranges from a light brown through various shades of brown to almost jet black in the nonfibrous varieties. The latter often show shades of gray and blue due to the presence of clay and remains of fresh water shells.

Properties of Peat. Peat when freshly removed from the bog holds from seventy-five to eighty-five or even ninety per cent of water. Even air dried peat retains from ten to twenty-five per cent of water, the amount varying with climatic conditions and the purity and physical constitution of the peat. In general, the freer from impurities and more fibrous the peat, the more water

retained. It was early observed that animal organisms imbedded in peat were preserved indefinitely. It is due to this antiseptic property that peat itself is preserved from decay.

Occurrence. Most of the peat deposits in Iowa occur in shallow depressions, but occasional peat deposits may be found on gently sloping hillsides, marking a line of seeping springs. The latter are usually of too small extent to be commercially considered. The first type only receives attention in this paper. Various terms have been and are being applied to peat deposits in Iowa. Perhaps the most common are bog, marsh and swamp. The late Professor N. S. Shaler used the term morass in his published writings for similar deposits. Professor C. A. Davis in his report on the Michigan* Peat Deposits uses the above terms for certain specific types of undrained areas. He defines a bog "as an area of wet, porous land on which the soil is made up principally of decayed and decaying vegetable matter, so loosely consolidated, and containing so much water, that the surface shakes and trembles as one walks over it. The vegetation upon the surface is variable, but it is characteristically either some species of moss or of sedge, or grass, or a combination of two or more of these with shrubs and even small trees." A marsh he states "has a firm soil that is not easily shaken when walked upon, although it may be soft and very wet, even submerged, and the vegetation upon it is principally grass-like, that is, with long narrow leaves, and weak, short-lived aerial stems. Shrubs may occur upon marshes, and where they are present not infrequently form thickets." A swamp as described by Davis "has trees and shrubby plants as the most important part of the vegetation, the soil being, as in the case of the marsh, firm, but wet, even, at times, to flooding." It is apparent even to casual observers that there can be no sharp line of separation according to Davis' definitions between the bog, the marsh, and the swamp.

In many cases two or even all of the above types may be represented in the same basin. Practically all of the Iowa peat accumulations worthy of mention belong to the bog type. Swamps as defined by Professor Davis are unknown in Iowa, at least in the peat producing district. All of the peat bogs of

^{*}Annual Report, Geological Survey of Michigan, 1906, pp. 108, et seq.

commercial importance are confined to the Wisconsin drift sheet, and by far the most important bogs are within the Altamont morainal belt on the east side of the Wisconsin lobe. The bogs vary greatly in area and depth. They range in area up to 1,500 acres and in depth to more than thirty-five feet. The deepest bogs tested are in those morainal tracts where the surface is most broken. Away from the morainal belt the basins become shallower and the peat thinner and as a general rule poorer in quality.

Mode of Accumulation. In many of the shallower basins water plants grow directly from the bottom and peat is accumulated through the successive generations of plants. Most of the bogs in the interior of the Wisconsin drift lobe are of this type. In the deeper bogs the filling is done by the growth of plants from the edges and to some extent from plants which grow on top of the water. The plant border extends itself as a mat over the surface of the water and eventually covers the entire surface of the lake or pond with a floating vegetable mat. Bear Lake in Winnebago county is an example of a lake being slowly transformed into a bog by the extension of the border mat. Sample holes put down at some distance from the open water disclosed a heavy fibrous layer underlain by a very soft peaty mud. The usual sequence in the deeper bogs is a brown, highly fibrous layer or surface mat resting on a non-fibrous to slightly fibrous brownish black mud or muck. In many instances this sequence is repeated, and below the peat mud is a second brown fibrous horizon followed by a second layer of peaty mud. Marly to clayer layers are not infrequently interspersed with the purer peat.

Peat Plants. Professor L. H. Pammel has prepared a list of the leading plants which contribute to the production of Iowa peat deposits. Suffice it to say that while in high latitudes and high altitudes the club mosses, Sphagnums and Hypnums contribute very largely toward the accumulation of peat, grasses and sedges are much more important in Iowa peat bogs. Mosses are present occasionally, but play a secondary role. Michigan and Wisconsin bogs support heavy growths of timber in many cases, but Iowa bogs are remarkably free from the growth of trees and shrubs.

Rate of Growth. The rate of accumulation is variable, but must be extremely slow, especially where the smaller plants predominate and there is but little increase through wash. In Iowa, as the chief deposits are in the Wisconsin drift, the filling has probably been going on since the retreat of that ice sheet. The deepest bogs probably exceed thirty-five feet but little. Assuming the minimum time estimate since the disappearance of the Wisconsin ice and the maximum thickness of bog, the maximum rate of accumulation would be about one foot of peat in about two hundred years. The average rate is undoubtedly much less.

Composition of Iowa Peat. Both chemical and calorimetric analyses were made of the peat samples collected. Chemically, Iowa peat runs high in ash and comparatively low in the combustible elements. The leading impurities are quartz sand, and clay, and lime carbonate derived from the remains of small fresh water molluscs.

The Goose Lake peat bog near Fertile in Worth county may be considered fairly representative of the best grade of Iowa peat bogs. An average sample of the air-dried machine peat put upon the market by the Fertile Peat and Clay Company gave the following composition:

Moisture	. 9.59	per	cent
Volatile carbons	. 27.50	per	cent
Fixed carbon	. 39.17	per	cent
Ash	. 23.74	per	cent
Total	.100.00	per	cent

An analysis of ash from the above sample gave the following results:

Silica	10.98	per	cent
Ferric oxide and alumina	8.42	per	${\tt cent}$
Lime	2.87	per	${\tt cent}$
Magnesia	0.60	per	cent
· -			
	22.87	per	${\tt cent}$
Total ash	.23.74	per	${\tt cent}$

In this particular case the leading impurity is clay with some lime. On account of the prevailingly high percentages of ash, the heat values run correspondingly low. The high percentage of ash in Iowa peat as compared with Michigan, Ontario and Maine peat, as well as the increase in ash toward the southwest in the Iowa field, is believed to be due largely to wind blown silt and clay. The prairie character of the Iowa bogs would interfere less with wind work than the timbered areas to the north and east.

The Heat Value of Iowa Peat. Davis in his work on Michigan peat shows that, in general, the heat value of peat varies inversely as the amount of ash present, but that there are many exceptions to the rule. The same rule applies to Iowa peat. A casual inspection of the analyses appended herewith is convincing and the dependence of heat value to ash is obvious. The range is from about 8,400 British Thermal Units down to peats so low in combustible matter that the charge fails to explode in the calorimeter. The average Iowa peat has about one-half the heat value of the average Iowa coal.

METHODS OF PREPARING PEAT FOR THE MARKET

Cut Peat. In Western Europe peat has long been used as a fuel by the common people. The method earliest employed and still used extensively was to cut the peat into rectangular blocks which were ricked up on or near the bog and permitted to air dry. This method involves no treatment whatever, and the product is known as cut peat. Only the fibrous varieties can be used in this way. On account of the bulkiness of the product and loss in handling, the use of cut peat is limited to the immediate vicinity of the bog. The cut peat retains from twenty to forty per cent of moisture.

Machine Peat. The essential features in the production of machine peat are that the peat is treated either in the bog or after its removal from the bog, with or without the addition of water, and then moulded by hand or by machinery. The simplest possible method is where the peat after being cut loose is worked into a pulp by the tramping of men or animals. Then it is moulded into blocks of convenient size and shape and dried in air. Machine peat generally means the use of machinery, and in those plants considered up-to-date, the removal from the pit, the reduction to a peat pulp, and the final moulding into blocks are

all done by machinery. A considerable number of excavators, conveyors, tempering and moulding machines have been invented and are in use in western and northern Europe. Some of these have been imported, modified, and are in use on the North American continent. The leading foreign types take the names of their inventors, and are the Schlickeysen,* R. Dolberg, A. Heinen, L. Lucht, A. Anrep, Svedala, and Akerman. In all of the above the peat is reduced to a pulp by passing through a machine resembling either the disintegrater or the pug mill, or both, used in preparing clay in ordinary brick plants. The peat plant near Fertile in Worth county has installed a Heinen machine.

In all of the above machines the peat pulp issues as a continuous bar, is received on pallets, is cut into convenient lengths and removed to the drying field or drier. As a rule artificial heat is not used in the drying of machine peat. The air dried machine peat retains from fifteen to thirty per cent of moisture.

Briquetted Peat. In both cut peat and machine peat the low density and consequent bulkiness and low fuel value of the product, its high moisture content and friable character not only render transportation and repeated handling unprofitable but practically prohibit them. To overcome these difficulties, a number of briquetting machines have been devised and put into use. The fundamental processes in briquetting consist of first removing a pertice of the water from the peat, after which it is passed through a disintegrator, screened, thoroughly dried in a rotary or plate drier, and then put through the briquette machine. A plunger working in a die subjects each briquette momentarily to a pressure of from 15,000 to 30,000 pounds per square inch. The resultant product possesses nearly the density of bituminous coal and is but slowly affected by the weathering agencies.

Attempts have been made to briquette peat direct from the pit, but without success. No mechanical device has yet been found by which the water can be removed directly.

^{*}Peat and Lignite, their Manufacture in Europe; by E. Nystrom, Canada Department of Mines, Mines Branch, pp. 58-84; Ottawa, 1908.

USES OF PEAT

As a Fuel. The principal use of peat has been and is as a fuel. It may be used direct as cut peat, machine peat, or briquettes, or may be transformed into coke, half coke, producer gas, or powder before burning. The latter two methods deserve most consideration at present for Iowa peat. Producer gas has been used much more extensively in western Europe than in the United States, and especially is this true of producer gas generated from peat. The gas obtained from peat compares very favorably in quality and heat value with that obtained from coal. Nystrom* reports that peat used as a powder and containing seventeen per cent of water gave nearly the same energy as the same weight of Newcastle coal. Peat as a source of producer gas must be of interest to north central Iowa where other fuel is scarce.

In the production of producer gas from peat, tar and ammonium sulphate may be recovered as by-products.

Minor Uses of Peat. On account of its high absorbent power it is used as stable litter, as a deodorizer and disinfectant, as an antiseptic and absorbent in surgery. It is also used as a fertilizer for lands deficient in humus. Fibrous peat is used as a packing material, for paving and building block, and artificial lumber, and for the manufacture of paper, and even woven into cloth.

USES OF IOWA PEAT

As a Fuel. From a casual inspection of the table of chemical analyses it is obvious that a great majority of the samples of Iowa peat analyzed carry upwards to twenty-five per cent of ash. According to Davis in his report on Michigan peat bogs, peat carrying more than twenty or twenty-five per cent of ash is too low grade to be considered commercially. Samples carrying up to thirty or thirty-five per cent burn readily and may be considered a serviceable fuel where other fuels are scarce. Such low grade fuel could not be shipped far from the bog in competition with Iowa and Illinois coals. It is possible that ways and means may be found to transform the peat into power through the producer gas engine and transmit it electrically to points where needed, or into a gas and pipe it from the bog to the consumer.

^{*}Peat & Lignite, Etc.; Canada Dept. Mines, pp. 171 and 172, and 198 et seq.; Ottawa, 1908.

Davis reports that a ton of peat carrying twenty to twenty-five per cent of moisture treated by the Ziegler process yields 6,650 cubic feet of gas, while the best English cannel coals yield scarcely twice as much gas. The cost per thousand feet is decidedly in favor of the peat. The peat coke is far superior to the gas coke on account of its freedom from sulphur and other objectionable impurities.

The ordinary gas producers now on the market in the United States are not adapted for the use of peat. Several of the large manufacturers of producers are at work on the problem and a producer which will successfully use peat is confidently expected in the near future.

The peat machined at Fertile and Dows kindles readily, burns without clinkers, and gives fair satisfaction for domestic purposes.

For Other Purposes. A sample of peat from the Fertile plant was sent to the Pilgrim Paper Company, Capac, Michigan, for examination, but was pronounced unsuited for the manufacture of paper pulp. The brown, highly fibrous layer found in the majority of Iowa bogs ought to furnish material sufficiently fibrous for a paper pulp. This superficial layer varies from two or three feet up to eight or ten feet in thickness. On account of its high absorptive capacity, it ought to find a ready sale for litter and packing material as straw and excelsior become scarcer.

TABLE I

Shows location by county, township, and section; acreage, average depth, and character of drainage of the more important Iowa peat bogs. The last column contains sample numbers representing each bog and corresponding to sample numbers in two tables following.

BIBLIOGRAPHY OF IOWA PEAT

COMPILED BY JAMES H. LEES.

Adair county, ancient peat bed in.

C. A. White, in Geol. Iowa, Vol. I, p. 339. 1870.

Buchanan county, peat in.

S. Calvin, in Ia. Geol. Surv., Vol. VIII, p. 247. 1897.

Beyer, S. W.

Briquetting of peat. Ia. Geol. Surv., Vol. XVIII, p. 28. 1907.

Calvin, S.

Fuel value of peat. Ia. Geol. Surv., Vol. XVII, p. 3. 1906.

Peat in Buchanan county. Ibid., Vol. VIII, p. 247. 1897.

Peat in Cerro Gordo county. Ibid., Vol. VII, p. 192. 1896.

Peat in Chickasaw county. Ibid., Vol. XIII, p. 289. 1902.

Peat in Pleistocene deposits of Iowa. Bull Geol. Soc. Am., Vol. 20, pp. 133-152. 1909.

· Cerro Gordo county, peat in.

S. Calvin, in Ia. Geol. Surv., Vol. VII, p. 192. 1896.

Chemical analyses of peat.

Rush Emery, in Geol. Iowa, Vol. II, pp. 397-402. 1870.

I. A. Williams, in Iowa Geol. Surv., Vol. XVI, p. 505. 1905.

Chickasaw county, peat in.

S. Calvin, in Ia. Geol. Surv., Vol. XIII, p. 289. 1902.

Davenport, ancient peat bed near.

W. H. Pratt, in Proc. Davenport Acad. Sci., Vol. I, pp. 96-99. 1876.

- C. A. White, in Geol. Iowa, Vol. I, p. 119. 1870.

Emery, Rush.

Chemical analyses of peat. Geol. Iowa, Vol. II, pp. 397-402. 1870.

Forest bed in northeastern Iowa.

W J McGee, in U. S. Geol. Surv., Eleventh Ann. Rept., pp 486-496. 1889-90. Franklin county, peat in.

I. A. Williams, in Iowa Geol. Surv., Vol. XVI, pp. 495, 504. 1905.

Fulton, A. R.

Peat in Iowa. Iowa: The Home for Immigrants, p. 24. Des Moines, 1870.

Humboldt county, peat in.

T. H. Macbride, in Ia. Geol. Surv., Vol. IX, p. 145. 1898.

Iowa City, ancient peat bed near.

C. A. White, in Geol. Iowa, Vol. I, p. 120. 1870.

Keyes, C. R.

Peat, formation of. Ia. Geol. Surv., Vol. II, p. 50. 1894.

Macbride, T. H.

Peat in Humboldt county. Ia. Geol. Surv., Vol. IX, p. 145. 1878. Pre-Kansan peat bed. Ia. Acad. Sci., Vol. IV, pp. 63-66. 1896.

McGee, W J.

Forest bed in northeastern Iowa. U. S. Geol. Surv., Eleventh Ann. Rept., pp. 486-496, 1889-90.

Peat, briquetting of.

S. W. Beyer, in Iowa Geol. Surv., Vol. XVIII, p. 28. 1907.

Peat, chemical analyses of.

Rush Emery, in Geol. Iowa, Vol. II, pp. 397-402. 1870.

I. A. Williams, in Ia. Geol. Surv., Vol. XVI, p. 505. 1905.

Peat, formation of.

C. R. Keyes, in Ia. Geol. Surv., Vol II, p. 50. 1894,

Peat, fuel value of.

S. Calvin, in Iowa Geol. Surv., Vol. XVII, p. 3. 1906.

Peat bed, ancient, in Adair county.

C. A. White, in Geol. Iowa, Vol. I, p. 339. 1870.

____, near Davenport.

W. H. Pratt, in Proc. Davenport Acad. Sci., Vol. I, pp. 96-99. 1876.

C. A. White, in Geol. Iowa, Vol. I, p. 119. 1870.

_____, near Iowa City.

C. A. White, in Geol. Iowa, Vol. I, p. 120. 1870.

Peat bed, buried.

T. E. Savage, in Iowa Acad. Sci., Vol. XI, pp. 103-109. 1903.

Peat bed, pre-Kansan.

T. H. Macbride, in Ia. Acad. Sci., Vol. IV, pp. 63-66. 1896.

Peat in Iowa.

A. R. Fulton, in Iowa: The Home For Immigrants, p. 24. Des Moines, 1870.

C. A. White, in Second Ann. Rept. State Geol., pp. 121-135. 1868.

History of Dallas county, p. 126. Des Moines, 1879. Also in several other county histories.

History of Davis county, p. 130. Des Moines, 1882. Also in several other county histories.

Peat in Pleistocene deposits of Iowa.

S. Calvin, in Bull. Geol. Soc. Am., Vol. 20, pp. 133-152. 1909.

Peat in Buchanan county.

S. Calvin, in Iowa Geol. Surv., Vol. VIII, p. 247. 1897.

Peat in Cerro Gordo county.

S. Calvin, Ibid., Vol. VII, p. 192. 1896.

Peat in Chickasaw county.

S. Calvin, Ibid., Vol. XIII, p. 289. 1902.

Peat in Franklin county.

I. A. Williams, Ibid., Vol. XVI, pp. 495, 504. 1905.

Peat in Humboldt county.

T. H. Macbride, Ibid., Vol. IX, p. 145. 1898.

Peat in Worth county.

I. A. Williams, Ibid., Vol. X, p. 375. 1899.

Peat resources of Iowa.

T. E. Savage, Ibid., Bull. 2, pp. 5-21. 1905.

Pratt, W. H.

Peat bed, ancient, near Davenport. Proc. Davenport Acad. Sci., Vol. I, pp. 96-99. 1876.

Pre-Kansan peat bed.

T. H. Macbride, in Iowa Acad. Sci., Vol. IV, pp. 63-66. 1896.

Savage, T. E.

Buried peat bed. Ia. Acad. Sci., Vol. XI, pp. 103-109. 1903. Peat resources of Iowa. Ia. Geol. Surv., Bull. 2, pp. 5-21. 1905.

White, C. A.

Peat bed, ancient, in Adair county. Geol. Iowa, Vol. I, p. 339. 1870.

- near Iowa City. Ibid., p. 120.

- near Davenport. Ibid., p. 119.

Peat in Iowa. Sec. Ann. Rept. State Geol., pp. 121-135. 1868.

Peat in Iowa. Geol. Iowa, Vol. II, pp. 275-288. 1870.

Williams, I. A.

Chemical analysis of peat. Ia. Geol. Surv., Vol. XVI, p. 505. 1905.

Peat in Franklin county. Ibid., Vol. XVI, pp. 495-504. 1905.

Peat in Worth county. Ibid., Vol. X, p. 375. 1899.

Worth county, peat in.

I. A. Williams, in Ia. Geol. Surv., Vol. X, p. 375. 1899.
